## Color singlets have integer electric charge:

Singlets are found only in the decomposition of reps. with triality zero:

1) The only invariants of $\mathrm{SU}(3)$ are $\delta_{j}^{i}$, $\varepsilon^{i j k}$, and $\varepsilon_{i j k}$.
2) All the irreps are found in the decomposition of the products of the fundamentals. In the case of $\mathrm{SU}(3)$, there are two fundamentals, 3 and $3^{*}$.
3) Start with an arbitrary product of $m$ factors of 3 and $n$ factors of $3^{*}$. The tensors that carry the rep. have components with $m$ indices of 3 type and $n$ of $3^{*}$ type. A singlet has no indices. To find a singlet (if it exists), we can contract with the invariants to try to get down to a non-vanishing tensor with no indices, i.e. a singlet.
4) Using $\delta_{j}^{i}$ reduces both m and n by one, while using $\varepsilon^{i j k}$, or $\varepsilon_{i j k}$ reduces either $m$ or $n$ by three. Thus in both cases the triality $=m-n \bmod 3$ does not change. Since $m=n=0$ for the singlet, its triality is zero, and it can be found only in a product that has triality zero.

If the triality is zero, then the electric charge is integer multiples of the proton charge:
Let $m_{U}$ be the number of up type quarks ( $u, c, t$ ), and let $m_{D}$ be the number of down type ( $\mathrm{d}, \mathrm{s}, \mathrm{b}$ ) quarks. For the anti-quarks, use $\mathrm{n}_{\mathrm{U}}$ and $n_{D}$. Also write $m=m_{U}+m_{D}$ and $n=n_{U}+n_{D}$. Then in units of the proton charge, the charge of a combination of quarks is

$$
\begin{aligned}
\mathrm{Q}= & (2 / 3) \mathrm{m}_{\mathrm{U}}-(1 / 3) \mathrm{m}_{\mathrm{D}}-(2 / 3) \mathrm{n}_{\mathrm{U}}+(1 / 3) \mathrm{n}_{\mathrm{D}} \\
& =(2 / 3)\left(\mathrm{m}_{\mathrm{U}}+\mathrm{m}_{\mathrm{D}}\right)-\mathrm{m}_{\mathrm{D}}-(2 / 3)\left(\mathrm{n}_{\mathrm{U}}+\mathrm{n}_{\mathrm{D}}\right)+\mathrm{n}_{\mathrm{D}} \\
& =(2 / 3)(\mathrm{m}-\mathrm{n})-\mathrm{m}_{\mathrm{D}}+\mathrm{n}_{\mathrm{D}},
\end{aligned}
$$

which is integer for triality zero.
